Studies on the molecular biology and biochemistry of chitin-binding proteins from marine organisms have been hampered by the lack of useful chitin-binding assays. We report here the development of two useful affinity assays for new crustacean chitin-binding proteins. (1) A competitive radioimmunoassay for chitin-binding protein was based on the use of radioiodinated chitin-binding protein immobilized on polyvinylchloride tubes as the solid phase in the sandwich assay. The limit of detection was 0.2 micrograms/ml. (2) A chitin-binding assay was based on a rapid lectin-dependent chitin-binding assay that was applied to immobilized chitin. The assay is sensitive, useful for testing crude proteins, and applicable to a variety of chitin-binding proteins. This invention relates to multi-port memories of the type used for storing digital signals representing transmitted or received data. There are many applications in which it is necessary to store and retrieve data signals of different types. For example, data can be represented by electrical signals of different voltages, or alternatively by electrical signals having different widths, or alternatively by a sequence of parallel data pulses with different widths. A conventional multi-port memory includes one or more groups of data input/output (I/O) lines or leads that are selectively addressed by a memory controller and which in turn select one or more memory cells in the memory to receive the data signals. The number of I/O leads depends on the number of data signals that are stored in the memory. There are many applications in which it is desirable to add additional 82157476af
